Introduction

Charts and graphs are often powerful ways to convey information to the reader. OpenOffice.org Calc offers a variety of chart and graph formats for your data.

Using Calc, you can customize charts and graphs to a considerable extent. Many of these options enable you to present your information in the best and clearest manner.

Creating a chart

To demonstrate the process of making charts and graphs in Calc, we will use the small table of data in Figure 1.

![Table of data for charting examples](image)

---

![Selecting data for plotting](image)

**Figure 1: Table of data for charting examples**

To create a chart, first highlight (select) the data to be included in the chart. The selection does not need to be in a single block, as shown in Figure 2; you can also choose individual cells or groups of cells (columns or rows). See Chapter 1 (Introducing Calc) for more about selecting cells and ranges of cells.

---

**Figure 2: Selecting data for plotting**
Next, open the Chart Wizard dialog using one of two methods.

- Choose **Insert > Chart** from the menu bar.
- Or, click the **Chart** icon on the main toolbar.

![Chart from main toolbar](image)

*Figure 3: Insert chart from main toolbar*

Either method inserts a sample chart on the worksheet, opens the Formatting toolbar, and opens the Chart Wizard, as shown in Figure 4.

**Tip**
Before choosing the Chart Wizard, place the cursor anywhere in the area of the data. The Chart Wizard will then do a fairly good job of guessing the range of the data. Just be careful that you have not included the title of your chart.

![Chart Wizard](image)

*Figure 4: Chart Wizard, Step 1—Choose a chart type*
Choosing a chart type

The Chart Wizard includes a sample chart with your data. This sample chart updates to reflect the changes you make in the Chart Wizard.

The Chart Wizard has three main parts: a list of steps involved in setting up the chart, a list of chart types, and the options for each chart type. At any time you can go back to a previous step and change selections.

Calc offers a choice of 10 basic chart types, with a few options for each type of chart. The options vary according to the type of chart you pick.

The first tier of choice is for two-dimensional (2D) charts. Only those types which are suitable for 3D (Column, Bar, Pie, and Area) give you an option to select a 3D look.

On the Choose a chart type page (Figure 4), select a type by clicking on its icon. The preview updates every time you select a different type of chart, and provides a good idea of what the finished chart will look like.

The current selection is highlighted (shown with a surrounding box) on the Choose a chart type page. The chart’s name is shown just below the icons. For the moment, we will stick to the Column chart and click on Next again.

Changing data ranges and axes labels

In Step 2, Data Range, you can manually correct any mistakes you have made in selecting the data.

On this page you can also change the way you are plotting the data by using the rows—rather than the columns—as data series. This is useful if you use a style of chart such as Donut or Pie to display your data.

Lastly, you can choose whether to use the first row or first column, or both, as labels on the axes of the chart.

You can confirm what you have done so far by clicking the Finish button, or click Next to change some more details of the chart.

We will click Next to see what we can do to our chart using the other pages of the Wizard.

Figure 5: Changing data ranges and axes labels
Selecting data series

On the Data Series page, you can fine tune the data that you want to include in the chart. Perhaps you have decided that you do not want to include the data for canoes. If so, highlight Canoes in the Data series box and click on Remove. Each named data series has its ranges and its individual Y-values listed. This is useful if you have very specific requirements for data in your chart, as you can include or leave out these ranges.

**Tip**
You can click the Shrink button next to the Range for Name box to work on the spreadsheet itself. This is handy if your data ranges are larger than ours and the Chart Wizard is in the way.

Another way to plot any unconnected columns of data is to select the first data series and then select the next series while holding down the Ctrl key. Or you can type the columns in the text boxes. The columns must be separated by semi-colons. Thus, to plot B3:B11 against G3:G11, type the selection range as B3:B11;G3:G11.

The two data series you are selecting must be in separate columns or rows. Otherwise Calc will assume that you are adding to the same data series.

Click **Next** to deal with titles, legend and grids.

### Adding or changing titles, legend, and grids

On the Chart Elements page (Figure 7), you can give your chart a title and, if desired, a subtitle. Use a title that draws the viewers’ attention to the purpose of the chart: what you want them to see. For example, a better title for this chart might be *The Performance of Motor and Other Rental Boats*.

It may be of benefit to have labels for the x-axis or the y-axis. This is where you give viewers an idea as to the proportion of your data. For example, if we put Thousands in the y-axis label of our graph, it changes the scope of the chart entirely. For ease of estimating data you can also display the x- or y- axis grids by selecting the Display grids options.
You can leave out the legend or include it and place it to the left, right, top or bottom. To confirm your selections and complete the chart, click Finish.

![Chart Title and Legend Settings](image)

**Figure 7: Titles, legend and grids**

### Editing charts

After you have created a chart, you may find things you would like to change. Calc provides tools for changing the chart type, chart elements, data ranges, fonts, colors and many other options, through the **Insert** and **Format** menus, the right-click (context) menu and the Chart toolbar.

#### Changing the chart type

You can change the chart type at any time. To do so:

1. First select the chart by double-clicking on it. The chart should now be surrounded by a gray border.
2. Then do one of the following:
   - Choose **Format > Chart Type** from the menu bar.
   - Click the chart type icon on the Formatting toolbar.
   - Right-click on the chart and choose **Chart Type**.

In each case, a dialog similar to the one in Figure 4 opens. See page 7 for more information.

#### Adding or removing chart elements

Figures 8 and 9 show the elements of 2D and 3D charts.

The default 2D chart includes only two of those elements:

- **Chart wall** contains the graphic of the chart displaying the data.
- **Chart area** is the area surrounding the chart graphic. The (optional) chart title and the legend (key) are in the chart area.
The default 3D chart also has the *chart floor*, which is not available in 2D charts.

**Figure 8**: Elements of 2D chart

**Figure 9**: Elements of 3D chart

You can add other elements using the commands on the **Insert** menu. The various choices open dialogs in which you can specify details.

First select the chart so the green sizing handles are visible. This is done with a single click on the chart.

The dialogs for Titles, Legend, Axes and Grids are self-explanatory. The others are a bit more complicated, so we’ll take a look at them here.
**Data labels**

Data labels put information about each data point on the chart. They can be very useful for presenting detailed information, but you need to be careful to not create a chart that is too cluttered to read.

Select the graph as described above and choose **Insert > Data Labels**. The options are as follows.

![Data Labels dialog](image)

**Figure 10: Data Labels dialog**

**Show value as number**
Displays the numeric values of the data points. When selected, this option activates the **Number format...** button.

**Number format...**
Opens the Number Format dialog, where you can select the number format. This dialog is very similar to the one for formatting numbers in cells, described in Chapter 2 (Entering, Editing, and Formatting Data).

**Show value as percentage**
Displays the percentage value of the data points in each column. When selected, this option activates the **Percentage format...** button.

**Percentage format...**
Opens the Number Format dialog, where you can select the percentage format.

**Show category**
Shows the data point text labels.

**Show legend key**
Displays the legend icons next to each data point label.

**Separator**
Selects the separator between multiple text strings for the same object.
**Placement**

Selects the placement of data labels relative to the objects.

Figure 22 on page 25 shows examples of values as text (neither *Show value as number* nor *Show value as percentage* selected) and values as percentages, as well as when data values are used as substitutes for legends or in conjunction with them.

**Trend lines**

When you have a scattered grouping of points in a graph, you may want to show the relationship of the points. A trend line is what you need. Calc has a good selection of regression types you can use for trend lines: linear, logarithm, exponential, and power. Choose the type that comes closest to passing through all of the points.

To insert trend lines for all data series, double-click the chart to enter edit mode. Choose **Insert > Trend Lines**, then select the type of trend line from *None*, *Linear*, *Logarithmic*, *Exponential*, or *Power*. You can also choose whether to show the equation for the trend line and the coefficient of determination ($R^2$).

To insert a trend line for a single data series, first select the data series in the chart, and then right-click and choose **Insert > Trend Line** from the context menu. The dialog for a single trend line is similar to the one below but has a second tab (Line), where you can choose attributes (style, color, width, and transparency) of the line.

![Trend Lines dialog](image)

*Figure 11: Trend Lines dialog*

To delete a single trend line or mean value line, click the line, then press the *Del* key.

To delete all trend lines, choose **Insert > Trend Lines**, then select *None*.

A trend line is shown in the legend automatically.

If you insert a trend line on a chart type that uses categories, such as Line or Column, then the numbers 1, 2, 3, ... are used as x-values to calculate the trend line.
The trend line has the same color as the corresponding data series. To change the line properties, select the trend line and choose **Format Trend Line**. This opens the **Line** tab of the Trend Lines dialog.

To show the trend line equation, select the trend line in the chart, right-click to open the context menu, and choose **Insert Trend Line Equation**.

When the chart is in edit mode, OpenOffice.org gives you the equation of the trend line and the correlation coefficient. Click on the trend line to see the information in the status bar. To show the equation and the correlation coefficient, select the line and choose **Insert R² and Trend Line Equation**.

For more details on the regression equations, see the topic **Trend lines in charts** in the Help.

**Mean value lines**

If you select the Mean Value Lines dialog from the Insert menu, Calc calculates the average of each selected data series and places a colored line at the correct level in the chart.

**Y error bars**

If you are presenting data that has a known possibility of error, such as social surveys using a particular sampling method, or you want to show the measuring accuracy of the tool you used, you may wish to show error bars on the chart. Select the chart and choose **Insert > Y Error Bars**.

Several options are provided on the Error Bars dialog. You can only choose one option at a time. You can also choose whether the error indicator shows both positive and negative errors, or only positive or only negative.

![Error Bars for all Data Series](image)

*Figure 12: Specifying the parameters of error bars*

- **Constant Value** - you can have separate positive and negative values.
- **Percentage** - choose the error as a percentage of the data points.
In the drop-down list:

- **Standard Error** - calculates the error based on the numerical data you provide in the chart
- **Variance** - shows error calculated on the size of the biggest and smallest data points
- **Standard Deviation** - shows error calculated on standard deviation
- **Error Margin** - you designate the error

- **Cell Range** - calculates the error based on cell ranges you select. The Parameters section at the bottom of the dialog changes to allow selection of the cell ranges.

### Formatting charts

The Format menu has many options for formatting and fine-tuning the appearance of your charts.

Double-click the chart so that it is enclosed by a gray border indicating edit mode; then, select the chart element that you want to format. Choose **Format** from the menu bar, or right-click to display a context menu relevant to the selected element. The formatting choices are as follows.

**Format Selection**

Opens a dialog in which you can specify the area fill, borders, transparency, characters, font effects, and other attributes of the selected element of the chart (see page 20).

**Position and Size**

Opens a dialog (see page 23).

**Arrangement**

Provides two choices: **Bring Forward** and **Send Backward**, of which only one may be active for some items. Use these choices to arrange overlapping data series.

**Title**

Formats the titles of the chart and its axes.

**Legend**

Formats the location, borders, background, and type of the legend.

**Axis**

Formats the lines that create the chart as well as the font of the text that appears on both the X and Y axes.

**Grid**

Formats the lines that create a grid for the chart.

**Chart Wall, Chart Floor, Chart Area**

These functions are described in the following sections.

**Chart Type**

Changes what kind of chart is displayed and whether it is two- or three-dimensional.
Data Ranges
Explained on page 7 (Figure 5 and Figure 6).

3D View
Formats 3D charts (see page 17).

Note
Chart Floor and 3D View are only available for a 3D chart. These options are unavailable (grayed out) if a 2D chart is selected.

In most cases you need to select the exact element you want to format. Sometimes this can be tricky to do with the mouse, if the chart has many elements, especially if some of them are small or overlapping. If you have Tooltips turned on (in Tools > Options > OpenOffice.org > General > Help, select Tips), then as you move the mouse over each element, its name appears in the Tooltip. Once you have selected one element, you can press Tab to move through the other elements until you find the one you want. The name of the selected element appears in the Status Bar.

Until OOo 3.2.1, axis labels and axis titles were included in the positioning rectangle of the chart. The space required for those labels depends on many factors like scaling, font, font size, and so on. To prevent the data plot itself from changing size and position, the labels are no longer included in the diagram size, so you can set the position and size of the plot area directly.

Note

Moving chart elements
You may wish to move or resize individual elements of a chart, independent of other chart elements. For example, you may wish to move the legend to a different place. Pie charts allow moving of individual wedges of the pie (in addition to the choice of “exploding” the entire pie).

1) Double-click the chart so that it is enclosed by a gray border.
2) Double-click any of the elements—the title, the legend, or the chart graphic. Click and drag to move the element. If the element is already selected, then move the pointer over the element to get the move icon (small hand), then click, drag and move the element.
3) Release the mouse button when the element is in the desired position.
**Note**

If your chart graphic is 3D, round red handles appear which control the three-dimensional angle of the graphic. You cannot resize or reposition the graphic while the round red handles are showing. With the round red handles showing, *Shift+Click* to get the green resizing handles. You can now resize and reposition your 3D chart graphic. See the following tip.

**Tip**

You can resize the chart graphic using its green resizing handles (*Shift+Click*, then drag a corner handle to maintain the proportions). However, you cannot resize the title or the key.

### Changing the chart area background

The chart area is the area surrounding the chart graphic, including the (optional) main title and key.

1. Double-click the chart so that it is enclosed by a gray border.
2. Choose **Format > Chart Area** or right-click on the chart area and choose **Format Chart Area**.
3. On the Chart Area dialog, choose the desired format settings.

On the *Area* tab, you can change the color, or choose a hatch pattern, bitmap or some preset gradients. Click on the drop-down box to see the options. Patterns are probably more useful than color if you have to print out your chart in black and white.

You can also use the *Transparency* tab to change the area’s transparency. If you used a preset gradient from the *Area* tab, you can see the different parameters of which it is composed.

![Chart Area dialog](image)

*Figure 13: Chart Area dialog*
Changing the chart graphic background

The chart wall is the area that contains the chart graphic.

1) Double-click the chart so that it is enclosed by a gray border.
2) Choose Format > Chart Wall. The Chart Wall dialog has the same formatting options as described in “Changing the chart area background” above.
3) Choose your settings and click OK.

Changing colors

If you need a different color scheme from the default for the charts in all your documents, go to Tools > Options > Charts > Default Colors, which has a much wider range of colors to choose from. Changes made in this dialog affect the default chart colors for any chart you make in future.

Formatting 3D charts

Use Format > 3D View to fine tune 3D charts. The 3D View dialog has three pages, where you can change the perspective of the chart, determine whether the chart uses the simple or realistic schemes or your own custom scheme, and the illumination that controls where the shadows will fall.

Rotation and perspective

To rotate a 3D chart or view it in perspective, enter the required values on the Perspective tab of the 3D View dialog. You can also rotate 3D charts interactively; see page 19.

![3D View dialog]

*Figure 14: Rotating a chart*

Here are some hints for using the Perspective tab:

- Set all angles to 0 for a front view of the chart. Pie charts and donut charts are shown as circles.
- With Right-angled axes enabled, you can rotate the chart contents only in the X and Y direction; that is, parallel to the chart borders.
• An x value of 90, with y and z set to 0, provides a view from the top of the chart. With x set to -90, the view is from the bottom of the chart.
• The rotations are applied in the following order: x first, then y, and z last.
• When shading is enabled and you rotate a chart, the lights are rotated as if they are fixed to the chart.
• The rotation axes always relate to the page, not to the chart’s axes. This is different from some other chart programs.
• Select the Perspective option to view the chart in central perspective as through a camera lens instead of using a parallel projection.
• Set the focus length in the box next to the Perspective option (it becomes active when you select the option). 100% gives a perspective view where a far edge in the chart looks approximately half as big as a near edge.

**Appearance**

Use the Appearance page to modify some aspects of a 3D chart's appearance.

*Figure 15: Modifying appearance of 3D chart*

Select a scheme from the list box. When you select a scheme, the options and the light sources are set accordingly. If you select or deselect a combination of options that is not given by the Realistic or Simple schemes, you can create a Custom scheme.

Select Shading to use the Gouraud method for rendering the surface, which applies gradients for a smoother, more realistic look. Otherwise, a flat method is used. The flat method sets a single color and brightness for each polygon. The edges are visible, soft gradients and spot lights are not possible. Refer to the Draw Guide for more details on shading.

Select Object Borders to draw lines along the edges.

Select Rounded Edges to smooth the edges of box shapes. In some cases this option is not available.
**Illumination**

Use the *Illumination* page (Figure 16) to set the light sources for the 3D view. Refer to the *Draw Guide* for more details on setting the illumination.

Click any of the eight buttons to switch a directed light source on or off. By default, the second light source is switched on. It is the first of seven normal, uniform light sources. The first light source projects a specular light with highlights.

For the selected light source, you can then choose a color and intensity in the list just below the eight buttons. The brightness values of all lights are added, so use dark colors when you enable multiple lights.

![Figure 16: Setting the illumination](image)

Each light source always points at the middle of the object initially. To change the position of the light source, use the small preview inside this page. It has two sliders to set the vertical and horizontal position of the selected light source.

The button in the corner of the small preview switches the internal illumination model between a sphere and a cube.

Use the *Ambient light* list to define the ambient light which shines with a uniform intensity from all directions.

**Rotating 3D charts interactively**

In addition to using the Perspective page of the 3D View dialog to rotate 3D charts, you can also rotate them interactively.

Select the Chart Wall, then hover the mouse pointer over a corner handle or the rotation symbol found in the middle of the chart’s information grid. The cursor changes to a rotation icon.

Press and hold the left mouse button and drag the corner in the direction you wish. A dashed outline of the chart is visible while you drag, to help you see how the result will look.
Formatting the chart elements

Depending on the purpose of your document, for example a screen presentation or a printed document for a black and white publication, you might wish to use more detailed control over the different chart elements to give you what you need.

To format an element, left-click on the element that you wish to change, for example one of the axes. The element will be highlighted with green squares. Then, right-click and choose an item from the context menu. Each chart element has its own selection of items. In the next few sections, we explore some of those options.

Formatting axes and inserting grids

Sometimes you need to have a special scale for one of the axes of your chart, or you need smaller grid intervals, or you want to change the formatting of the labels on the axis. After highlighting the axis you wish to change, right-click and choose one of the items from the pop-up menu.

Choosing **Format > Axis > X Axis** or **Format > Axis > Y Axis** opens the dialog shown in Figure 17, which in this case is the *Scale* tab. The fields available on this dialog depend on the type of chart and whether it is 2D or 3D.

On the *Scale* tab, you can choose a logarithmic or linear scale (default), how many marks you need on the line, where the marks are to appear and the increments (intervals) of the scale. You must first deselect the *Automatic* option in order to modify the value for any scale. Selecting the *Reverse direction* radial creates a backwards representation of the chart.

On the *Label* tab (Figure 18), you can choose whether to show or hide the labels and how to handle them when they won’t all fit neatly into one row (for example, if the words are too long).

Not shown here are the tabs with options for choosing a font and specific font effects, formatting the lines, positioning the elements of the line and interval marks, and selecting effects relating to Asian Typography if this function has been activated in **Tools > Options > Languages**.

![Figure 17: Formatting axis scales](image-url)
**Formatting data labels**

You can choose properties for the labels of the data series. Carefully click on the chart element, then right-click and choose the property you want to change. Choosing the command **Format Data Labels** opens a dialog with several tabs where you can change the color of the label text, the size of the font, and other attributes. The **Data Label** tab is shown in Figure 10.

On the **Data Label** tab, you can choose whether to:

- Show the labels as text
- Show numeric values as a percentage or a number
- Include the legend box as part of the label

The text for labels is taken from the column labels and it cannot be changed here. If the text needs to be abbreviated, or if it did not label your graph as you were expecting, you need to change it in the original data table.

**Hierarchical axis labels**

Multiple columns of categories are now displayed in a hierarchical manner at the axis as shown. To get that automatically while creating a chart, make sure that all the first columns (or rows) contain text and not only numbers. You can also choose to set the ranges for categories to multiple columns on the Data Series page in the Wizard or the Data Ranges dialog.
Choosing and formatting symbols

In line and scatter charts the symbols representing the points can be changed to a different symbol shape or color through the object properties dialog. Select the data series you wish to change, right-click, and choose Format Data Series from the context menu. You can reach this dialog by double-clicking the area of data you would like to change.

On the Line tab of the Data Series dialog, in the Icon section, choose from the drop-down list Select > Symbols. Here you can choose no symbol, a symbol from an inbuilt selection, a more exciting range from the gallery, or if you have pictures you need to use instead, you can insert them using Select > From file.

![Symbol selection](image)

**Figure 19: Symbol selection**

Adding drawing objects to charts

(New in OOo 3.3) As in the other OOo components, you can use the drawing toolbar to add simple shapes such as lines, rectangles, and text objects, or more complex shapes such as symbols or block arrows. This toolbar is located at the bottom of the screen and automatically appears when a chart is generated. Use these additional shapes to add explanatory notes to your chart as demonstrated in the figure below.

![Drawing objects](image)
To format the drawing objects, right-click and choose your changes from the context menu.

Resizing and moving the chart

You can resize or move all elements of a chart at the same time, in two ways: interactively or by using the Position and Size dialog. You may wish to use a combination of both methods: interactive for quick and easy changes, then the dialog for precise sizing and positioning.

To resize a chart interactively:
1) Click once on the chart to select it. Green sizing handles appear around the chart.
2) To increase or decrease the size of the chart, click and drag one of the markers in one of the four corners of the chart. To maintain the correct ratio of the sides, hold the Shift key down while you click and drag.

To move a chart interactively:
1) Click on the chart to select it. Green sizing handles appear around the chart.
2) Hover the mouse pointer anywhere over the chart. When it changes to the move icon, click and drag the chart to its new location.
3) Release the mouse button when the element is in the desired position.

Using the Position and Size dialog

To resize or move a chart using the Position and Size dialog:
1) Click on the chart to select it. Green sizing handles appear around the chart.
2) Right-click and choose Position and Size from the pop-up menu.
3) Make your choices on this dialog.

Figure 20: Defining the position and size of an object
Position is defined as a X,Y coordinate relative to a fixed point (the *base point*), typically located at the upper left of the document. You can temporarily change this base point to make positioning or dimensioning simpler (click on the spot corresponding to the location of the base point in either of the two selection windows on the right side of the dialog—upper for positioning or lower for dimensioning).

The possible base point positions correspond to the handles on the selection frame plus a central point. The change in position lasts only as long as you have the dialog open; when you close this dialog, Calc resets the base point to the standard position.

**Tip**  
The *Keep ratio* option is very useful. Select it to keep the ratio of width to height fixed while you change the size of an object.

Either or both the size and position can be protected so that they cannot be accidentally changed. Select the appropriate options.

**Tip**  
If you cannot move an object, check to see if its position is protected.

### Gallery of chart types

It's important to remember that while your data can be presented with a number of different charts, the message you want to convey to your audience dictates the chart you ultimately use. The following sections present examples of the types of charts that Calc provides, with some of the tweaks that each sort can have and some notes as to what purpose you might have for that chart type. For further details, see the OpenOffice.org Help index.

**Column charts**

*Column charts* are commonly used for data that shows trends over time. They are best for charts that have a relatively small number of data points. (For a larger time series, a line chart would be better.) It is the default chart type, as it is one of the most useful charts and the easiest to understand.

**Bar charts**

*Figure 21: Three bar graph treatments.*
Bar charts are excellent for giving an immediate visual impact for data comparison in cases when time is not an important factor, for example when comparing the popularity of a few products in a marketplace.

- The first chart in Figure 21 is achieved quite simply by using the chart wizard with Insert > Grids, deselecting y-axis, and using Insert > Mean Value Lines.
- The second chart in the figure is the 3D option in the chart wizard with a simple border and the 3D chart area twisted around.
- The third chart in the figure is an attempt to get rid of the legend and put labels showing the names of the companies on the axis instead. We also changed the colors to a hatch pattern.

Pie charts

Pie charts are excellent when you need to compare proportions. For example, a pie chart would be ideal if you needed to figure out comparisons of departmental spending, what the department spent on different items or what different departments spent. These charts work best with smaller numbers of values, no more than about half a dozen. Any more than this and the visual impact starts to fade.

As the Chart Wizard guesses the series that you wish to include in your pie chart, you might need to adjust this initially on the Wizard’s Data Ranges page if you know you want a pie chart or by using the Format > Data Ranges > Data Series dialog.

You can do some interesting things with a pie chart, especially if you make it into a 3D chart. It can then be tilted, given shadows, and generally turned into a work of art.

You can choose an option in the Chart Wizard to explode the pie chart, but this is an all-or-nothing option. If your aim is to accentuate one piece of the pie, you can separate out one piece by carefully highlighting it after you have finished with the Chart Wizard, and dragging it out of the group. When you do this, you might need to enlarge the chart area again to regain the original size of the pieces.

Figure 22: Pie charts

The effects achieved in Figure 22 are explained below.

- The first example is a 2D pie chart with one part of the pie exploded. To produce this type of chart, first choose Insert > Legend and deselect Display legend. Choose Insert > Data Labels and choose Show value as number. Then carefully select the piece you wish to highlight, move the cursor to the edge of the piece and click (the piece will have nine green highlight squares to mark it), and then drag it out from the rest of the pieces. The pieces will
decrease in size, so you need to highlight the chart wall and drag it at a corner to increase the size.

- The second example is a 3D pie chart with realistic schema and illumination. With a completed 2D pie chart, choose **Format > 3D view > Illumination** where you can change the direction of the light, the color of the ambient light, and the depth of the shade. We also adjusted the 3D angle of the disc in the **Perspective** dialog on the same set of tabs.

  The chart updates as you make changes, so you can immediately see the effects.

  If you want to separate out one of the pieces, click on it carefully; you should see a wire frame highlight. Drag it out with the mouse and then, if necessary, increase the size of the chart wall.

- The third example is a 3D pie chart with different fill effects in each portion of the pie. Choose **Insert > Data labels** and select **Show value as percentage**. Carefully select each of the pieces so that it has a wire frame, then highlight and right-click to get the object properties dialog. Choose the **Area** tab. For one of the pieces we chose a bitmap effect, for another we selected a gradient feature and for the third we used the **Transparency** tab and adjusted the transparency to 50%.

**Donut charts**

*Donut charts* are a variation on the pie chart. To create one, choose Pie in the Chart Type dialog, and choose the third or fourth type of pie chart. For more variety, consider selecting **3D Look**.

![Figure 23: Choosing a donut chart](image)
**Area charts**

An *area chart* is a version of a line or column graph. It may be useful where you wish to emphasize volume of change. Area charts have a greater visual impact than a line chart, but the data you use will make a difference.

![Figure 24: Examples of donut charts](image)

As shown in Figure 25, an area chart is sometimes tricky to use. This may be one good reason to use transparency values in an area chart. After setting up the basic chart using the Chart Wizard, do the following:

- Right-click on the y-axis and choose **Delete Major Grid**. As the data overlaps, some of it is lost behind the first data series. This is not what you want. A better solution is shown in the highlighted chart below and is explained in the next point.

- After deselecting the y-axis grid, right-click on each data series in turn and choose **Format Data Series**. On the **Transparency** tab, set Transparency to 50%. The transparency makes it easy to see the data hidden behind the first data series. Now, right-click on the x-axis and choose **Format Axis**. On the Label tab, choose **Tile** in the **Order** section and set the Text orientation to 55 degrees. This places the long labels at an angle.

- To create the third variation, after doing the steps above, right-click and choose **Chart Type**. Choose the **3D Look** option and select **Realistic** from the drop-
down list. We also twisted the chart area around and gave the chart wall a picture of the sky. As you can see, the legend turns into labels on the z-axis. But overall, though it is visually more appealing, it is more difficult to see the point you are trying to make with the data.

Other ways of visualizing the same data series are represented by the stacked area chart or the percentage stacked area chart.

Figure 26: Stacked and percentage stacked area charts

The first does what it says: each number of each series is added to the others so that it shows an overall volume but not a comparison of the data. The percentage stacked chart shows each value in the series as a part of the whole. For example in June all three values are added together and that number represents 100%. The individual values are a percentage of that. Many charts have varieties which have this option.

Line charts

A line chart is a time series with a progression. It is ideal for raw data, and useful for charts with plentiful data that show trends or changes over time where you want to emphasize continuity. On line charts, the x-axis is ideal to represent time series data.

Figure 27: Line charts
Scatter or XY charts

Scatter charts are great for visualizing data that you have not had time to analyze, and they may be the best for data when you have a constant value against which to compare other data. Examples of good scatter charts might include weather data, reactions under different acidity levels, conditions at altitude or any data which matches two series of numeric data. In contrast to line charts, the x-axis is to the left of the right labels, which usually indicates a time series.

Scatter charts may surprise those unfamiliar with how they work. While constructing the chart, if you choose Data Range > Data series in rows, the first row of data represents the x-axis. The rest of the rows of data are then compared against the first row data. Figure 28 shows a comparison of three currencies with the Japanese Yen. Even though the table presents the monthly series, the chart does not. In fact the Japanese Yen does not appear; it is merely used as the constant series that all the other data series are compared against.

Bubble charts

A bubble chart is a variation of a scatter chart in which the data points are replaced with bubbles. It shows the relations of three variables in two dimensions. Two variables are used for the position on the X-axis and Y-axis, while the third is shown as the relative size of each bubble. One or more data series can be included in a single chart.

Bubble charts are often used to present financial data. The data series dialog for a bubble chart has an entry to define the data range for the bubbles and their sizes.

Gallery of chart types
Net charts

A net chart is similar to a polar or radar chart. It is useful for comparing data that is not a time series but shows different circumstances, such as variables in a scientific experiment or direction. The poles of the net chart are equivalent to the y-axes of other charts. Generally, between three and eight axes are best; any more and this type of chart becomes confusing. Before and after values can be plotted on the same chart, or perhaps expected and real results, so that differences can be compared.

Figure 30 shows two types of net charts:

- (Left): A plain net chart without grids or lines, only points.
- (Right): A net chart with lines, points and a grid. Axes colors and labels have been changed. The chart area color has been changed with a gradient effect. The points on this graph have been changed to fancy 3D spheres.

![Figure 30: Two net diagrams showing totally fabricated data from totally fictional experiments.](image)
Other varieties of a net chart can be made to show the data series as stacked numbers or stacked percentages. The series can also be filled with a color (Figure 31). Partial transparency is often best for showing all the series all at once.

![Figure 31: Filled net or radar chart](image)

**Stock charts**

A *stock chart* is a specialized column graph specifically for stocks and shares. You can choose traditional lines, candlestick, and two-column type charts. The data required for these charts is quite specialized, with series for opening price, closing price and high and low prices. In this type of chart, the x-axis represents a time series.

When you set up a stock chart in the Chart Wizard, the Data Series dialog is very important. You need to tell it which series represents the opening price, the closing price, the high and low price of the stock, and so on.

![Figure 32: Adjusting data series for stock charts.](image)

A nice touch is that OpenOffice.org stock charts color-code the rising and falling shares: white for rising and black for falling in the candlestick chart and red and blue in the traditional line chart.
**Column and line charts**

A *column and line chart* is a combination of two other chart types. It is useful for combining two distinct but related data series like sales over time (column) with a profit margin trends (line).

You can choose the number of columns and lines in the Chart Wizard. So for example you might have two columns with two lines to represent two product lines with the sales figures and profit margins of both.

The chart in Figure 33 has manufacturing cost and profit data for two products, over a period of time (six months in 2007). To create this chart, first highlight the table and start the Chart Wizard. Choose the Column and Line chart type with two lines and the data series in rows. Then give it a title to highlight the aspect you want to show. The lines are different colors at this stage and don’t reflect the product relationships. When you finish with the Chart Wizard, highlight the chart, click on the line, right-click and chose **Format Data Series**.

On this tab there are a few things to change: The colors should match the products so both Ark Manufacturing and its profit line are blue and Prall Manufacturing is red. The lines need to be more noticeable so make the lines thicker by increasing the width to 0.08.

![Figure 33: Column and line chart](image)

For the background, highlight the chart wall, right-click and choose **Format Wall**. On the *Area* tab, change the drop-down box to show Gradient. Choose one of the preset gradient patterns and make it lighter by going to the *Transparency* tab and making the gradient 50% transparent.

To make the chart look cleaner without the grid, go to **Insert > Grids** and deselect the X-axis option.
